Basic Monochrome Television System

TV scanning principle-Interlaced Scanning

A frame is divided into two fields to save bandwidth.

It takes advantages of the image retention of our eyes

Bandwidth Requirement

$$B_w = 0.8F_R N_L R_H$$

B_w = required bandwidth for a TV signal

F_R = number of frames or complete pictures transmitted each second

N_L = number of scanning lines

R_H = horizontal resolution defined to be number of pixel in horizontal dimension within Y , where Y is the picture height. (Note that H is not the picture width)

The 0.8 number is derived as follows:

$$B_w = (\text{Cycles per frame}) F_R$$

$$\text{Cycles per frame} = (N_L)(\text{Cycle per line})$$

$$\text{Cycle per line} = \frac{(0.5)(\text{AspectRatio})(R_H)}{0.84} = 0.8R_H$$

AspectRatio = the ratio of the image width to its height, here it is 4/3 for conventional TV. The AspectRatio of HDTV is 16/9.

0.5 is contributed by the interlaced scanning.

0.84 is the fraction of the horizontal scanning interval devote to signal transmission. (The remainder is utilized for horizontal blanking).

The trade-off between B_w , F_R , N_L , and R_H is a big concern for original TV design.

Scanning Standards

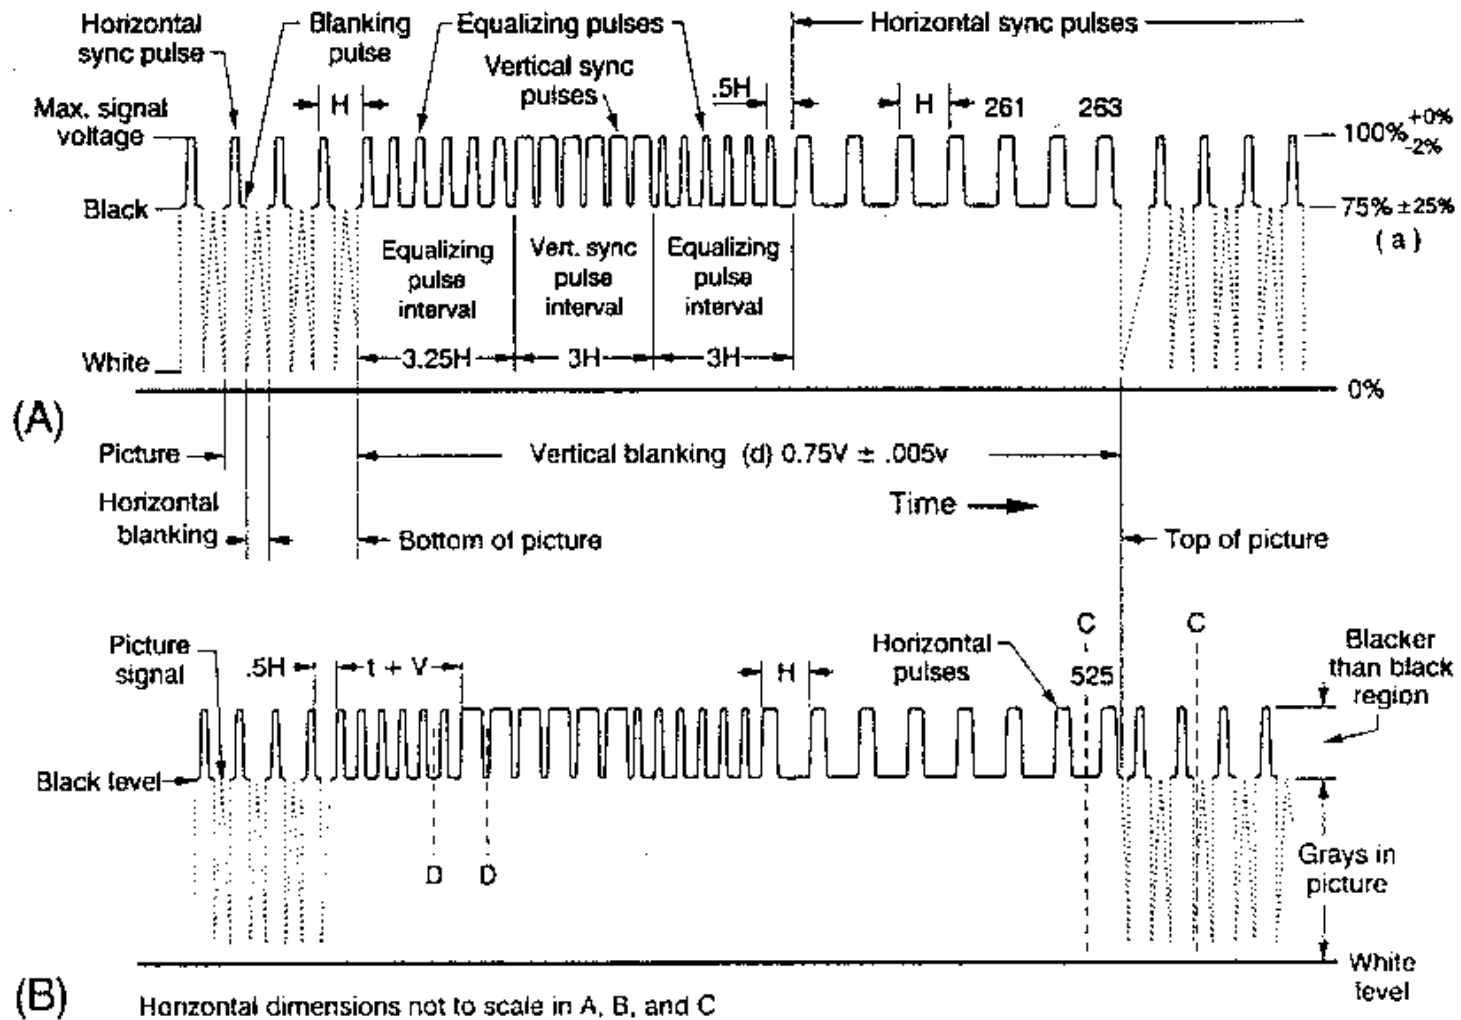

The frame rate must be larger enough to reduce flicker to an acceptable level. It is also needed to be multiple or submultiple of the primary power frequency so that the “humming” effect resulting from imperfect filtering of the power source are minimum.

TABLE 1.1 U.S. and Foreign Scanning Standards

| | Color type | Fields per second | Frames per second | Lines per frame | Lines per second |
|----------------------|------------|-------------------|-------------------|-----------------|-------------------|
| United States | | | | | |
| Monochrome | | 60 | 30 | 525 | 15,750 |
| Color | NTSC | 59.94 | 29.97 | 525 | 15,734 |
| England | | | | | |
| Monochrome | | 50 | 25 | 405 | 10,126 |
| Color | PAL | 50 | 25 | 625 | 15,625 |
| Japan | | | | | |
| Color | NTSC | 59.94 | 29.97 | 525 | 15,734 |
| France | | | | | |
| Monochrome | | 50 | 25 | 819 | 20,475 |
| Color | SECAM | 50 | 25 | 625 | 15,625 |
| Germany | | | | | |
| Color | PAL | 50 | 25 | 625 | 15,625 |
| Former USSR | | | | | |
| Color | SECAM | 50 | 25 | 625 | 15,625 |

Luminance Video Signal Waveform

Chrominance Signal Components

NTSC(National Television System Committee) uses AM and PM to insert the color information to the video signal. PAL (Phase Alternating Lines) and SECAM (Sequential Colour avec Memoire) use slightly different methods.

US TV Broadcast Channels regulated by FCC

TABLE 9.1 Television Broadcast Channels

| Channel | Frequency, MHz | Channel | Frequency |
|----------------------|----------------|---------|-----------|
| Low-Band VHF | | | |
| 2 | 54-60 | | |
| 3 | 60-66 | | |
| 4 | 66-72 | | |
| 5 | 76-82 | | |
| 6 | 82-88 | | |
| High-Band VHF | | | |
| 7 | 174-180 | | |
| 8 | 180-186 | | |
| 9 | 186-192 | | |
| 10 | 192-198 | | |

| | | 69 | 800-806 |

6MHz Standard US TV broadcast channel

It has two carriers, the visual carrier 1.25 MHz above the lower channel edge and the aural carrier 4.5 MHz above the visual. The visual carrier is amplitude-modulated by the video signal. The aural carrier is frequency-modulated with a peak deviation of $\pm 25\text{kHz}$ (compared to $\pm 75\text{kHz}$ for FM broadcasting).

Figure 9.1 Standard U.S. television broadcast channel.

Basic Image Quality Criteria

- **Image definition**—the distinctness of the outlines in the image; the degree to which the image appears to be “in-focus”; a measure of the sharpness of the transitions or edges between its dark and light areas.
In the high-definition system, these edge must be very sharp.
This quality criterium is where the High Definition TV gets its name.
It is closely related to **visual acruity**, the smallest angular separation at which individual lines can be distinguish.
- **Gray scale**—specified by three parameters:
 - highlight brightness—the brightness of the brightest area of the image
 - contrast ratio—the ratio of the brightness of the brightest area to that of the darkest, expressed in dB.
 - gamma—the slope of the image brightness as a function of the scene brightness.
- **Signal-to-Noise ratio**

Note that brightness is a subjective term that indicates the magnitude of the visual sensation produced by a source of light. **Weber’s Law: *The increase in stimulus necessary to produce an increase in sensation of any of our senses is not an absolute quantity but depends on the proportion that the increase bears to the immediately preceding stimulus.***

Image Defects (Some unique to TV images)

- Flicker—an effect results when the frame rate is not high enough to cause the eye to perceive a continuous image.
- Aliasing—the production of spurious signals as the result of sampling in space and time.
- Lag—a measure of the rate of change of the video signal at a fixed point on the raster when the scene changes. Big lag causes loss of resolution/trailing tail.
- Geometric distortion
- Hum—the interference caused by spurious power source voltages.
- Co-channel interference—two TV stations operating on the same frequency, alternating black and white horizontal bars across the picture.
- Receiver-generated interference
- Ghosts a duplicate of the main image, slightly displaced from it, usually to the right, and much fainter. It is caused by multipath transmission (reflection of building or mountain). A 1000-ft path difference would produce a displacement of $1/63$ of the scanning line length.

Bandwidth and Horizontal Resolution

The R_H , horizontal limiting resolution of TV, the number of black and white vertical lines that can be distinguished in a dimension equal to the picture height.

$$R_H = \frac{2C_H B_w}{A_R N_L F_R}$$

C_H = fraction of time each scanning line devoted to the transmission of picture information after subtracting the time required for horizontal blanking

B_w = system bandwidth

A_R = aspect ratio

N_L = total number of scanning lines per frame

F_R = frame rate per second

| | NTSC | PAL | HDTV |
|---------------------------|------------------------|------------------------|-------------------------|
| B_w (MHz) | 4.2 | 5.0 | 20 |
| N_L | 525 | 625 | 1125 |
| C_H | 0.85 | 0.80 | 0.83 |
| Aspect ratio | 1.33 ($\frac{4}{3}$) | 1.33 ($\frac{4}{3}$) | 1.78 ($\frac{16}{9}$) |
| F_R (frames per second) | 29.97 | 25 | 30 |
| R_H (lines) | 340 | 409 | 593 |

Scanning lines and vertical resolution

The R_V , vertical limiting resolution of TV, the number of vertical lines that can be distinguished in a dimension equal to the picture height, is limited by the number of active (visible) scanning lines but not equal to it, because the vertical detail in the image is randomly located w.r.t. the scanning line

$$R_V = C_V K_f N_L$$

C_V = fraction of scanning line that are visible (after subtracting the lines that are removed by vertical blanking)

K_f = Kell factor, the ratio of vertical resolution to the number of scanning lines

N_L = total number of scanning lines

| | NTSC | PAL | HDTV |
|---------------|------|------|------|
| C_V | 0.92 | 0.92 | 0.96 |
| N_L | 525 | 625 | 1125 |
| K_f | 0.7 | 0.7 | 0.7 |
| R_V (lines) | 343 | 408 | 767 |

Picture elements (pixels)

N_p , is the number of pixel is broadcast TV system

$$N_p = \frac{2CK_f B_w}{F_R}$$

C = fraction of time occupied by active scanning (after subtracting vertical and horizontal blanking periods)

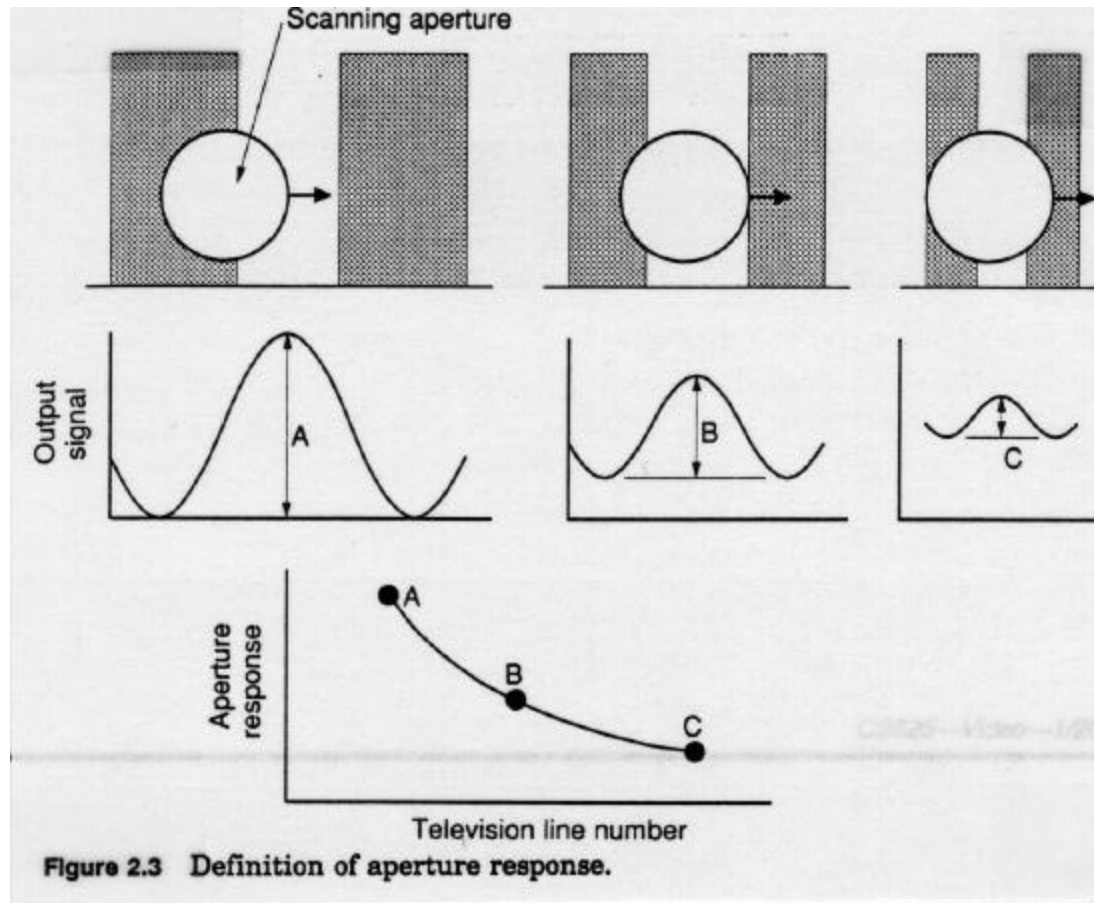

NSTC TV system has 148000 pixels

HDTV system has 743000 pixels.

Aperture Response

a universal criterion for specifying picture definition and other image system performance, including that of films, lens, TV camera imagers, video amplifier, scanning process, receiver picture tubes, and the human eye.

Equivalent line number N_e

An aperture curve is the most complete indication of the definition of a system. N_e is a number trying to approximate the overall definition. It is the line number that defines a rectangle having the same area as the area under the aperture response squared curve.

Aperture Response of TV Broadcast System

Comparison of Film and Television Performance

TABLE 2.3 Comparison of Film and Television Performance

| | Limiting resolution | N_e |
|------------|---------------------|-------|
| 16-mm film | 1100 | 300 |
| NTSC TV | | |
| Horizontal | 312 | 310 |
| Vertical | 312 | 310 |
| 35-mm film | 1800 | 450 |
| HDTV | | |
| Horizontal | 553 | 513 |
| Vertical | 767 | 481 |

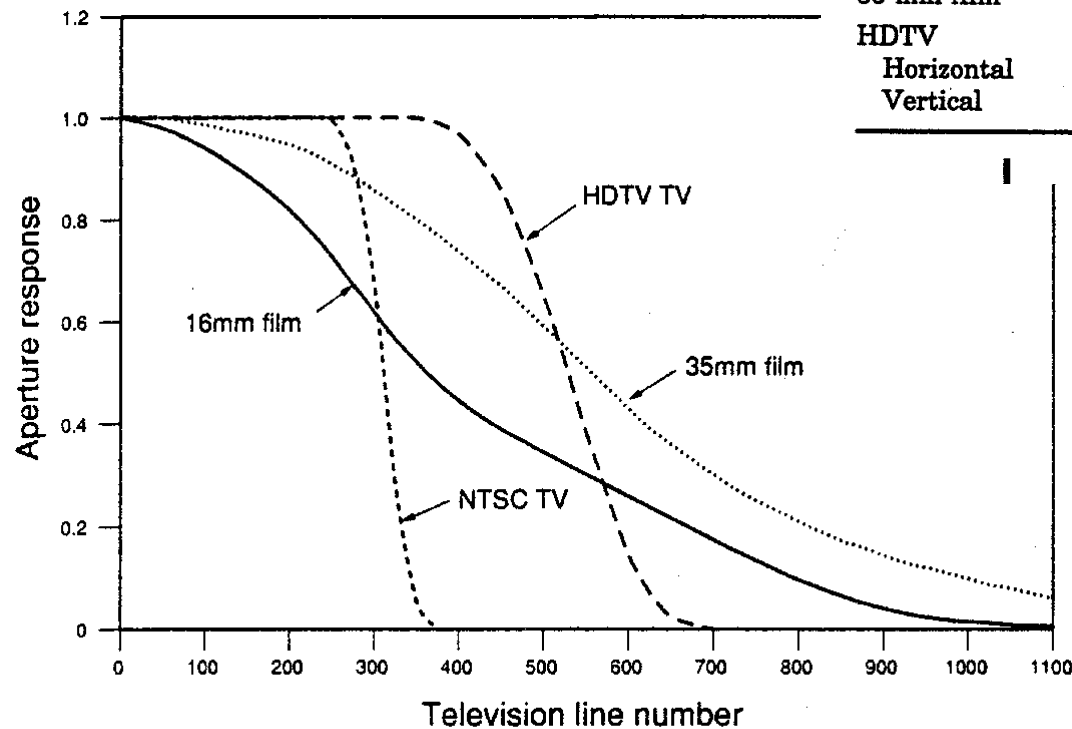

Figure 2.14 Comparison of television and film aperture response.

Color Video Signal

Color has a dual meaning

- a physical property of visible light
- the perception of this property by human vision.

Each pixel in a color image has three basic properties
luminance, hue, and saturation in objective terms, and
brightness, color, purity in corresponding perceptual terms.

Hue, Wavelength, and Saturation

The following table is based on monochromatic light (light with single wavelength)

| Hue | Approximate wavelength, nm |
|--------|----------------------------|
| Violet | 400 |
| Blue | 450 |
| Cyan | 490 |
| Green | 520 |
| Yellow | 575 |
| Orange | 590 |
| Red | 640 |

The colors that appear in nature are polychromatic (mixture of many wavelength)

The wavelength of a visible light ranges from 400 to 780 nm.

White and gray light results when the radiation at all wavelengths is present in approximately equal amount.

Saturation the ratio of the magnitude of the energy in the spectral (dominant wavelength) component to the total energy of the light. A pure spectral color has a saturation of 100%, while the saturation of white or gray light is 0%.

The appearance of any color can be duplicated by a mixture of white or gray light and a pure spectral color in the proper proportions.

Subtractive and Additive Primary Colors

Photography and painting are subtractive color systems. The picture or scene is illuminated by an external source of light with many hues. The hue of the image is produced by the subtraction of color components by absorption. The subtractive primaries are magenta, yellow, and cyan. Since magenta has a reddish cast and cyan is bluish, it is popularly (and erroneously) stated that the primary colors are red, yellow, and blue.

TABLE 3.2 Subtractive Primaries

| Primary | Reflects or transmits | Absorbs |
|---------|-----------------------|---------|
| Magenta | Red and blue | Green |
| Yellow | Red and green | Blue |
| Cyan | Blue and green | Red |

Color TV is an additive system, since it produces hues by adding the primary color components. The additive primaries are red, blue, green.

TABLE 3.3 Additive Primaries

| Combinations | Hue of combination |
|-----------------|--------------------|
| Red plus green | Yellow |
| Blue plus green | Cyan |
| Blue plus red | Magenta |

Define Color using CIE Chromaticity Coordinates

Using three color matching functions to produce X, Y, Z tristimulus values.

$$X = 380 \int_{380}^{780} L(\lambda)x'(\lambda)d\lambda$$

$$Y = 380 \int_{380}^{780} L(\lambda)y'(\lambda)d\lambda$$

$$Z = 380 \int_{380}^{780} L(\lambda)z'(\lambda)d\lambda$$

The chromaticity coordinates, x and y are calculated by

$$x = \frac{X}{X + Y + Z}$$

$$y = \frac{Y}{X + Y + Z}$$

CIE (Comité Internationale de l'Eclairage)

The CIE Chromaticity Diagram

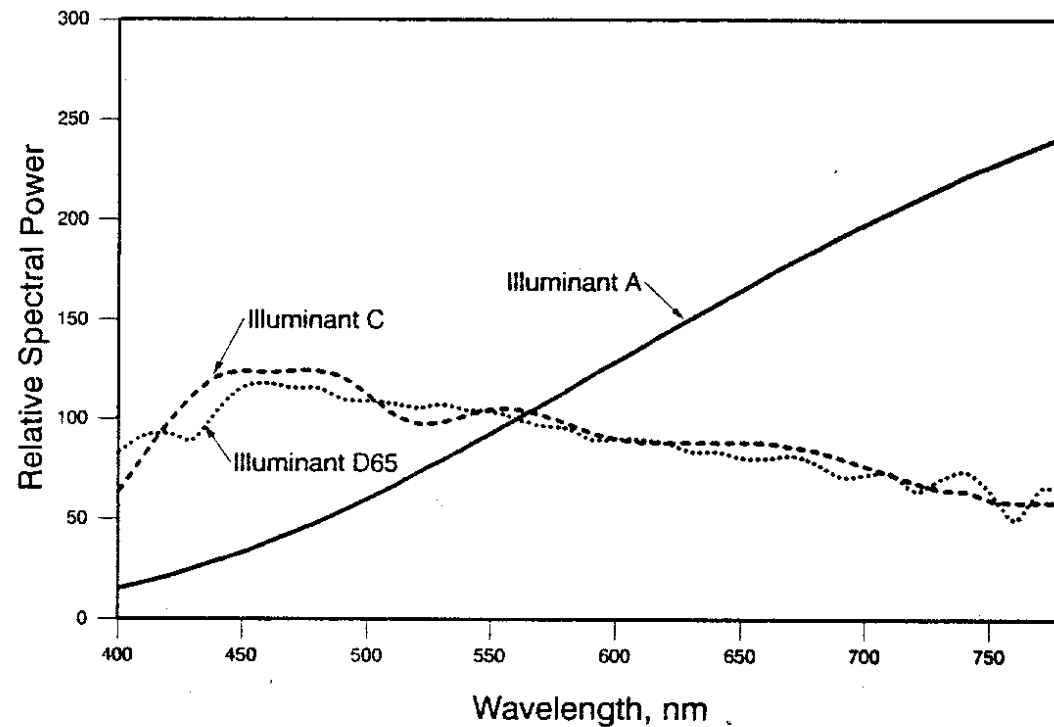

Figure 3.3 The CIE Chromaticity Diagram.

Standard illuminants

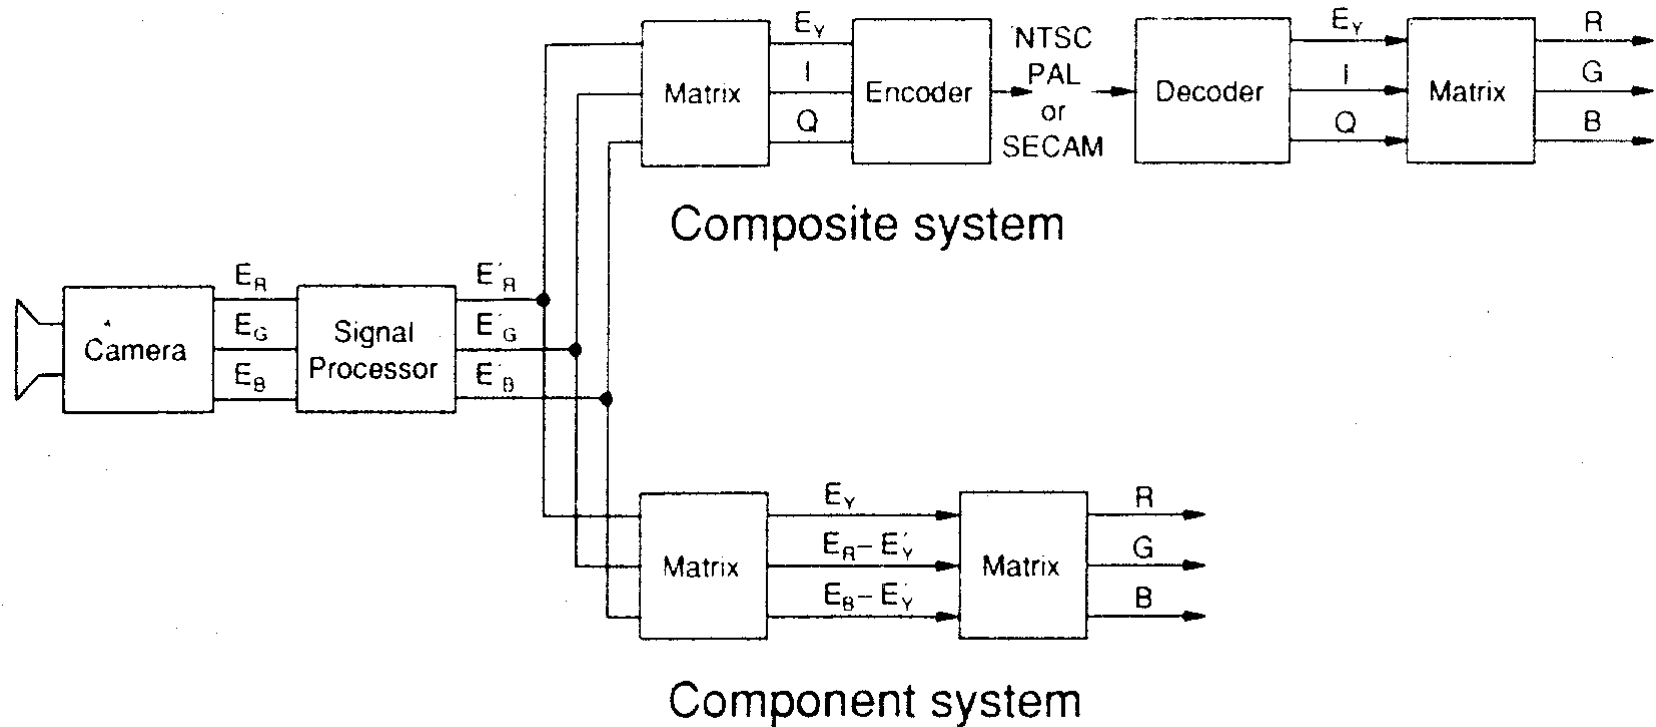

TABLE 3.4 Chromaticity Coordinates of Standard Illuminants

| Designation | Source | x | y |
|----------------------------|--------------------|--------|--------|
| Illuminant A | Tungsten at 2856 K | 0.4476 | 0.4074 |
| Illuminant C | Daylight | 0.3101 | 0.3516 |
| Illuminant D ₆₅ | Daylight (revised) | 0.3127 | 0.3290 |

Analog Color TV System Configuration

Video Signal Formats for Color

Color can be specified by luminance, Y , and color difference, $R-Y$ and $B-Y$ components.

NTSC uses Y, I, Q format.

PAL uses Y, U, V format.

The three signal components in each format are generated by the gamma-corrected signal E_R', E_G' and E_B' .

In all formats, the luminance signal component, E_Y' is generated by

$$E_Y' = 0.299E_R' + 0.587E_G' + 0.114E_B'$$

The coefficients of the components E_R', E_G' , and E_B' are based on the relative sensitivity of the human eye to the primary colors. E_Y' is then proportion to the perceived brightness of the scene.

NTSC use $E_I' = 0.60E_R' - 0.28E_G' - 0.32E_B'$ called I signal (orange-cyan)

$$E_Q' = 0.21E_R' - 0.51E_G' + 0.30E_B'$$
 called Q signal (green-magenta)

The ability of the eye to discern fine detail is less in colors than for monochrome, and it is less for magenta than for orange. NTSC take advantages of this.

PAL chrominance signal component

PAL systems have 5-5.5 MHz video bandwidth. They use YUV format.

$$E_{U'} = 0.493(E_{B'} - E_{Y'})$$

$$E_{V'} = 0.877(E_{B'} - E_{Y'})$$

TABLE 3.7 Color Television System Bandwidths

| Country | System | Bandwidth, MHz |
|-------------------------|--------|-------------------|
| United States, Japan | NTSC | 4.2 |
| Canada, Mexico | NTSC | 4.2 |
| Great Britain | PAL | 5.5 |
| Germany, Austria, Italy | PAL | 5.0 |
| France | SECAM | 6.0 |
| Former USSR | SECAM | 6.0 |

Digital TV

A commonly used format for composite signals

- sampling rate at 4 time subcarrier frequency, or 14.4 MHz (NTSC).
- use 8-bit word to encode each sample.
- the bit rate is 115.2Mbits/s. (very high)

TABLE 4.2 Sampling Frequencies

| Designations: | NTSC, SMPTE D-2 | | PAL, SMPTE D-2 |
|--|-----------------|-----------|----------------|
| | $3f_{sc}$ | $4f_{sc}$ | $4f_{sc}$ |
| Composite Signals | | | |
| Bandwidth, MHz | 4.2 | 4.2 | 5.5 |
| Subcarrier frequency (f_{sc}), MHz | 3.58 | 3.58 | 4.43 |
| Sampling frequency, MHz | 10.6 | 14.4 | 17.7 |
| Samples per total line | 674 | 915 | 1132 |
| Samples per active line | 557 | 757 | 939 |
| Bit rate, Mbits/s (8-bit words) | 85.9 | 114.5 | 141.9 |

Sampling Frequency for Component Signals

| Component Signals | | |
|----------------------------------|--|---|
| | 525 lines, 59.95 fields | 625 lines, 50 fields |
| Designations: | SMPTE D-1 SMPTE RP 125 CCIR 601 4-2-2 | SMPTE D-1 EBU 3246/3247 CCIR 601 4-2-2 |
| Luminance channel | | |
| Bandwidth, MHz | 5.5 | 5.5 |
| Sampling frequency, MHz | 13.5 | 13.5 |
| Samples per total line | 858 | 864 |
| Samples/active line | 710 | 716 |
| Bit rate, Mbits/s | 108.0 | 108.0 |
| Color difference channels | | |
| Bandwidth, MHz | 2.2 | 2.2 |
| Sampling frequency, MHz | 6.75 | 6.75 |
| Samples per total line | 429 | 432 |
| Samples per active line | 355 | 358 |
| Bit rate, Mbits/s (8-bit words) | 54.0 | 54.0 |
